

Climate Resilience Zoning Task Force, April 2019
 Discussion Framework: Flooding Predictions, Impacts, and Development Strategies

| | Flooding Projections | Flooding Impacts | Land Use and Development Strategies |
|--|---|---|--|
| <p>Questions for Task Force</p> | <p>1. What type of flooding should this process focus on? 2. What levels of flooding (e.g. % storm per time horizon) should be prioritized for protection and/or recovery?</p> | <p>3. What flooding impacts should this group focus on? What flooding impacts are of most concern?</p> | <p>4. What strategies might property owners employ to mitigate flooding impacts, and what are the relevant benefits and costs of these strategies?</p> |
| <p>Key concepts and content for consideration</p> | <p style="text-align: center;"><i>Relevant content from the city's Climate Change Vulnerability and Adaptation work</i></p> <p>Key types of flooding facing Cambridge:</p> <ul style="list-style-type: none"> • Precipitation/riverine: <ul style="list-style-type: none"> ○ More immediate issue, likely to intensify over time ○ Effects in areas scattered throughout city ○ Infrastructure for storage/drainage is a significant factor • Sea level rise/storm surge <ul style="list-style-type: none"> ○ Not a significant issue until mid-century ○ Effects primarily in Alewife area ○ Infrastructure factors include dams, barriers (storage/drainage has limited effect) <p>Modeling time horizons used in the CCVA:</p> <ul style="list-style-type: none"> • 2030 predictions: more immediate • 2070 predictions: longer-term, based on no action taken, could change if improvements are made <p>The CCVA modeled different elevation probabilities in the 2030 and 2070 time horizons:</p> <ul style="list-style-type: none"> • 10% / 10-year: likely to recur during building's lifespan • 1% / 100-year: happens rarely during building lifespan • 0.2% / 500-year: possible, but not likely, to occur during building lifespan (not studied in CCPR) <p>Flooding duration:</p> <ul style="list-style-type: none"> • Likely less than a day at predicted levels • Could vary depending on duration of event, reliability of infrastructure | <p style="text-align: center;"><i>Examples of types of possible flooding impacts</i></p> <p>Impacts to buildings/uses (existing and new):</p> <ul style="list-style-type: none"> A. Electrical/mechanical system failures B. Damage to structures and/or contents from water – potentially intensified by salt water in storm surge C. Differing considerations based on use type: <ul style="list-style-type: none"> a. Residential: emergency services, access, habitability during power outage, exposure to mold or contaminants if residential units flood b. Commercial: business closure, loss of goods c. Parking: damage to vehicles, contamination d. Hospitals, police, fire: continuity of emergency services <p>Broader impacts (beyond parcel-scale):</p> <ul style="list-style-type: none"> D. Sewer/stormwater service E. Electric/gas/other utilities F. Street usability/accessibility (pedestrians, bicycles, vehicles, emergency vehicles) G. Public transportation services H. Emergency services | <p><i>Land use scenarios for which this Task Force's work could apply:</i></p> <ul style="list-style-type: none"> • Continuation or alteration of existing buildings and uses <ul style="list-style-type: none"> ○ Not making change (with its own impact) ○ Protecting what exists ○ Making changes (which make impacts better or worse) • Redevelopment of individual sites / new projects <ul style="list-style-type: none"> ○ Best practices for new projects • Large-scale planned redevelopment <ul style="list-style-type: none"> ○ Opportunities in larger projects that involve infrastructure and public amenities <p><i>Strategies (refer to CCPR Preparedness Handbook):</i></p> <ul style="list-style-type: none"> • Elevate structures or specific uses/functions (e.g., utilities) • Flood-proof structures (“dry floodproofing”) • Provide floodwater storage on site (e.g., compensatory storage) • Provide stormwater storage or infiltration (e.g., DPW detention/retention standards) via grey or green infrastructure • Use materials that can withstand flooding (“wet floodproofing”) or be repaired/replaced • Install pumps to prevent water from getting in or remove it • Install backup power or utilities (e.g. generator, on-site solar/battery) • Design for “passive resilience” to maintain life safety and comfort (e.g. ventilation, heating/cooling) without power • Provide community facilities at a building or neighborhood scale • Provide planning or programming for emergency shelter, support services, evacuation • Design to enable buildings and sites to adapt to future conditions (e.g., taller ground floors that can be built up, ability to convert electrical/mechanical systems) <p><i>Benefits, costs & considerations re: land-owner strategies to address flooding</i></p> <ul style="list-style-type: none"> • Temporary vs. permanent measures • Where to protect (which timeframe, probability, type of flooding) • What uses need what level or type of protection? (e.g., residential, commercial, utilities/mechanicals, parking, emergency facilities) • Level of difficulty of implementing • Co-benefits such as mitigation or open space • Resilience impact • Cost to implement • Trade-offs with other planning goals such as housing, urban design & economic development. |
